Writing Plan

1. Create a mail API with Vue and AJAX using the POST request.
2. Sending the mail form data to a PHP script via Fetch and the POST request.
3. Handle both success and failure via the response object and changes to the UI.

Inspirations:

Validate the form content on the server side using the PHP script that was created in class. Return a success or failure message object to your Fetch handler(s) and update your UI appropriately.

Handle failure first. Use the $refs object that Vue provides - the references to the DOM elements / fields in the form - to mark which are missing/empty/incorrect. If the AJAX request is successful, add some visual cue / UX to view - the content of the page.
